

L06 – Architectural Design

Topics covered

- ✧ Architectural design decisions
- ✧ Architectural views
- ✧ Architectural patterns

Architectural design

- ✧ Architectural design is concerned with understanding how a software system should be organized and designing the overall structure of that system.
- ✧ Architectural design is the critical link between design and requirements engineering, as it identifies the main structural components in a system and the relationships between them.
- ✧ The output of the architectural design process is an architectural model that describes how the system is organized as a set of communicating components.

Agility and architecture

- ✧ It is generally accepted that an early stage of agile processes is to design an overall systems architecture.
- ✧ Refactoring the system architecture is usually expensive because it affects so many components in the system

Architectural abstraction

- ✧ Architecture in the small is concerned with the architecture of individual programs. At this level, we are concerned with the way that an individual program is decomposed into components.
- ✧ Architecture in the large is concerned with the architecture of complex enterprise systems that include other systems, programs, and program components. These enterprise systems are distributed over different computers, which may be owned and managed by different companies.

Advantages of explicit architecture

✧ Stakeholder communication

- Architecture may be used as a focus of discussion by system stakeholders.

✧ System analysis

- Means that analysis of whether the system can meet its non-functional requirements is possible.

✧ Large-scale reuse

- The architecture may be reusable across a range of systems
- Product-line architectures may be developed.

Architectural representations

- ✧ Simple, informal block diagrams showing entities and relationships are the most frequently used method for documenting software architectures.
- ✧ But these have been criticised because they lack semantics, do not show the types of relationships between entities nor the visible properties of entities in the architecture.
- ✧ Depends on the use of architectural models. The requirements for model semantics depends on how the models are used.

Box and line diagrams

- ✧ Very abstract - they do not show the nature of component relationships nor the externally visible properties of the sub-systems.
- ✧ However, useful for communication with stakeholders and for project planning.

Use of architectural models

- ✧ As a way of facilitating discussion about the system design
 - A high-level architectural view of a system is useful for communication with system stakeholders and project planning because it is not cluttered with detail. Stakeholders can relate to it and understand an abstract view of the system. They can then discuss the system as a whole without being confused by detail.
- ✧ As a way of documenting an architecture that has been designed
 - The aim here is to produce a complete system model that shows the different components in a system, their interfaces and their connections.

Architectural design decisions

Architectural design decisions

- ✧ Architectural design is a creative process so the process differs depending on the type of system being developed.
- ✧ However, a number of common decisions span all design processes and these decisions affect the non-functional characteristics of the system.

Architectural design decisions

Architecture reuse

- ✧ Systems in the same domain often have similar architectures that reflect domain concepts.
- ✧ Application product lines are built around a core architecture with variants that satisfy particular customer requirements.
- ✧ The architecture of a system may be designed around one of more architectural patterns or 'styles'.
 - These capture the essence of an architecture and can be instantiated in different ways.

Architecture and system characteristics

✧ Performance

- Localise critical operations and minimise communications. Use large rather than fine-grain components.

✧ Security

- Use a layered architecture with critical assets in the inner layers.

✧ Safety

- Localise safety-critical features in a small number of sub-systems.

✧ Availability

- Include redundant components and mechanisms for fault tolerance.

✧ Maintainability

- Use fine-grain, replaceable components.

Architectural views

Architectural views

- ✧ What views or perspectives are useful when designing and documenting a system's architecture?
- ✧ What notations should be used for describing architectural models?
- ✧ Each architectural model only shows one view or perspective of the system.
 - It might show how a system is decomposed into modules, how the run-time processes interact or the different ways in which system components are distributed across a network. For both design and documentation, you usually need to present multiple views of the software architecture.

Architectural views

4 + 1 view model of software architecture

- ✧ A logical view, which shows the key abstractions in the system as objects or object classes.
- ✧ A process view, which shows how, at run-time, the system is composed of interacting processes.
- ✧ A development view, which shows how the software is decomposed for development.
- ✧ A physical view, which shows the system hardware and how software components are distributed across the processors in the system.
- ✧ Related using use cases or scenarios (+1)

Architectural patterns

Architectural patterns

- ✧ Patterns are a means of representing, sharing and reusing knowledge.
- ✧ An architectural pattern is a stylized description of good design practice, which has been tried and tested in different environments.
- ✧ Patterns should include information about when they are and when they are not useful.
- ✧ Patterns may be represented using tabular and graphical descriptions.

Layered architecture

- ✧ Used to model the interfacing of sub-systems.
- ✧ Organises the system into a set of layers (or abstract machines) each of which provide a set of services.
- ✧ Supports the incremental development of sub-systems in different layers. When a layer interface changes, only the adjacent layer is affected.
- ✧ However, often artificial to structure systems in this way.

The Layered architecture pattern

Name	Layered architecture
Description	Organizes the system into layers with related functionality associated with each layer. A layer provides services to the layer above it so the lowest-level layers represent core services that are likely to be used throughout the system. See Figure 6.6.
Example	A layered model of a system for sharing copyright documents held in different libraries, as shown in Figure 6.7.
When used	Used when building new facilities on top of existing systems; when the development is spread across several teams with each team responsibility for a layer of functionality; when there is a requirement for multi-level security.
Advantages	Allows replacement of entire layers so long as the interface is maintained. Redundant facilities (e.g., authentication) can be provided in each layer to increase the dependability of the system.
Disadvantages	In practice, providing a clean separation between layers is often difficult and a high-level layer may have to interact directly with lower-level layers rather than through the layer immediately below it. Performance can be a problem because of multiple levels of interpretation of a service request as it is processed at each layer.

Repository architecture

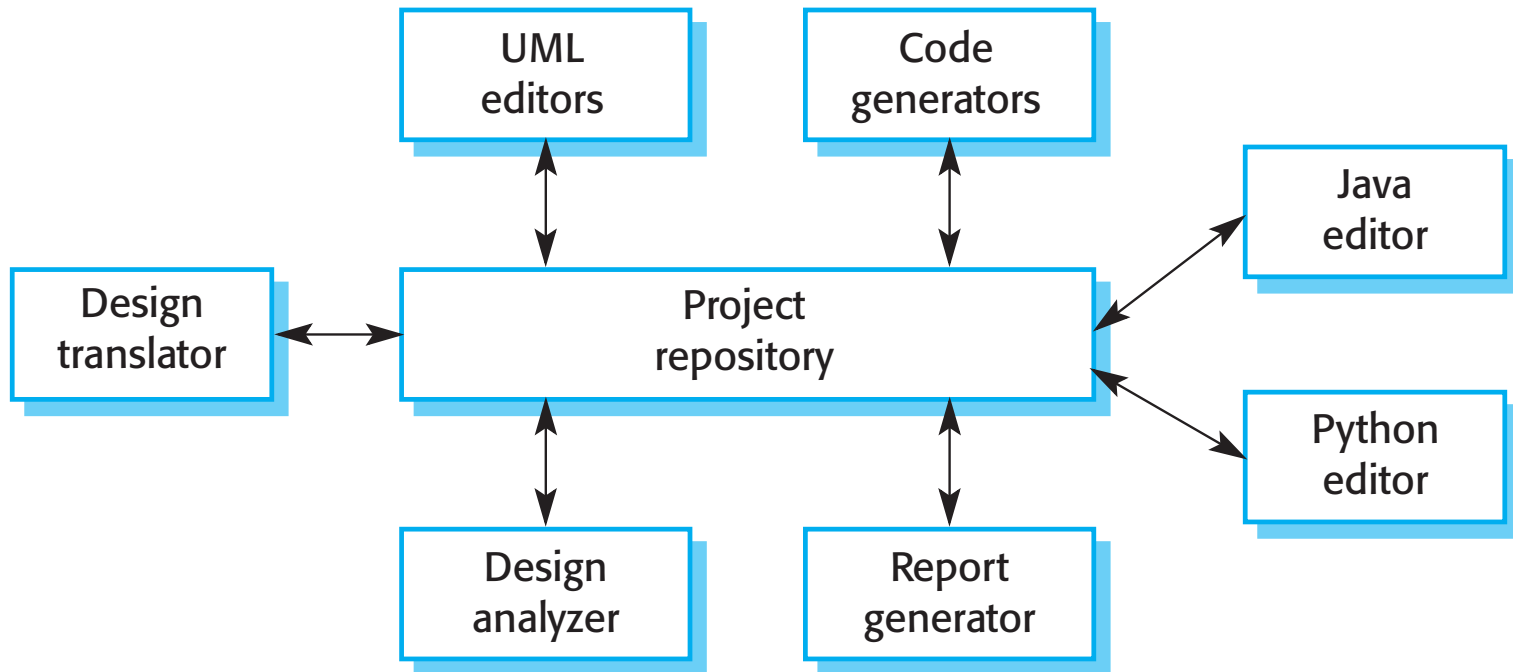

- ✧ Sub-systems must exchange data. This may be done in two ways:
 - Shared data is held in a central database or repository and may be accessed by all sub-systems;
 - Each sub-system maintains its own database and passes data explicitly to other sub-systems.
- ✧ When large amounts of data are to be shared, the repository model of sharing is most commonly used as this is an efficient data sharing mechanism.

The Repository pattern

Name	Repository
Description	All data in a system is managed in a central repository that is accessible to all system components. Components do not interact directly, only through the repository.
Example	Figure 6.9 is an example of an IDE where the components use a repository of system design information. Each software tool generates information which is then available for use by other tools.
When used	You should use this pattern when you have a system in which large volumes of information are generated that has to be stored for a long time. You may also use it in data-driven systems where the inclusion of data in the repository triggers an action or tool.
Advantages	Components can be independent—they do not need to know of the existence of other components. Changes made by one component can be propagated to all components. All data can be managed consistently (e.g., backups done at the same time) as it is all in one place.
Disadvantages	The repository is a single point of failure so problems in the repository affect the whole system. May be inefficiencies in organizing all communication through the repository. Distributing the repository across several computers may be difficult.

Client-server architecture

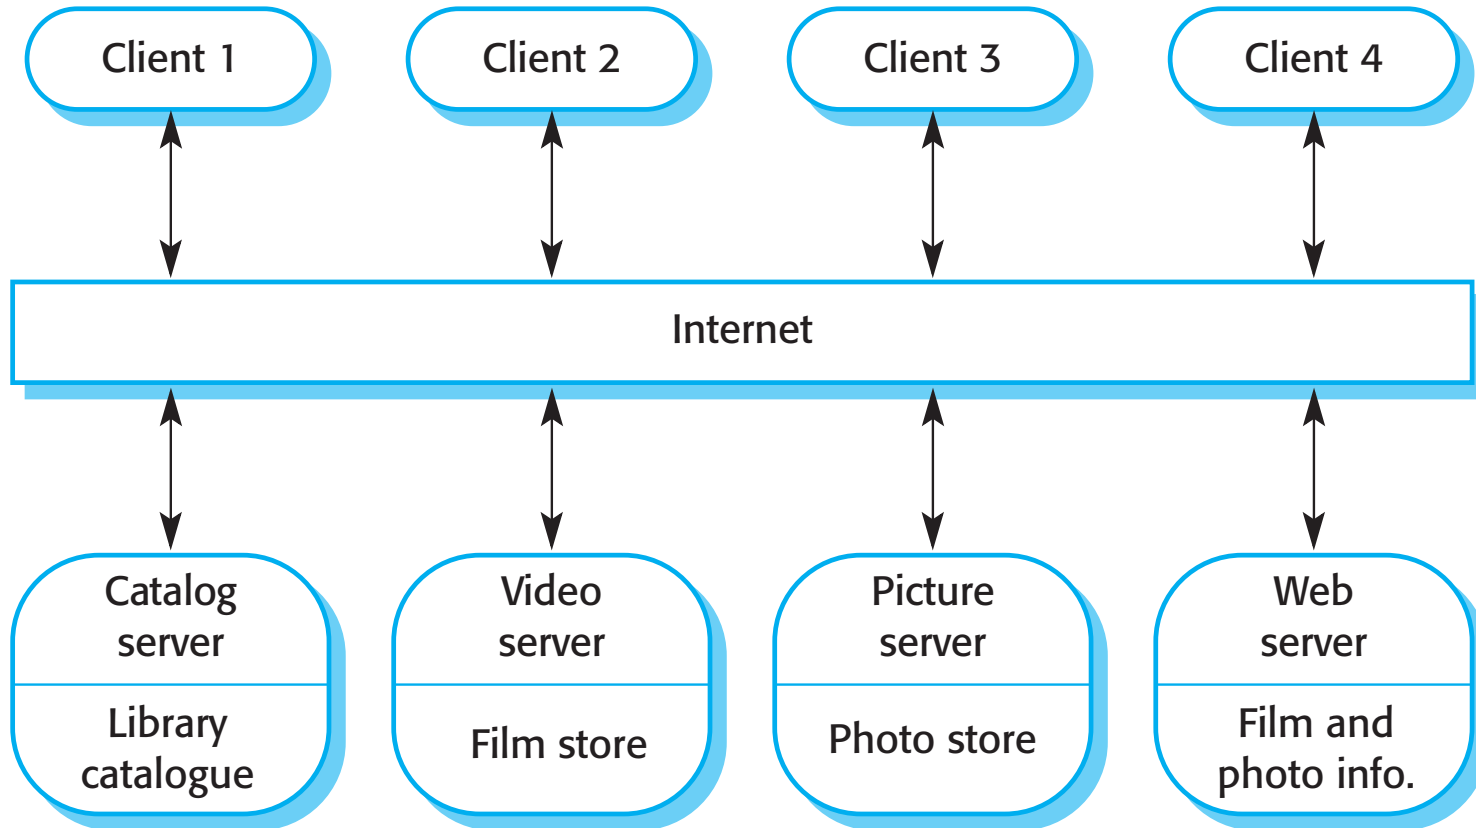

- ✧ Distributed system model which shows how data and processing is distributed across a range of components.
 - Can be implemented on a single computer.
- ✧ Set of stand-alone servers which provide specific services such as printing, data management, etc.
- ✧ Set of clients which call on these services.
- ✧ Network which allows clients to access servers.

The Client–server pattern

Name	Client-server
Description	In a client–server architecture, the functionality of the system is organized into services, with each service delivered from a separate server. Clients are users of these services and access servers to make use of them.
Example	Figure 6.11 is an example of a film and video/DVD library organized as a client–server system.
When used	Used when data in a shared database has to be accessed from a range of locations. Because servers can be replicated, may also be used when the load on a system is variable.
Advantages	The principal advantage of this model is that servers can be distributed across a network. General functionality (e.g., a printing service) can be available to all clients and does not need to be implemented by all services.
Disadvantages	Each service is a single point of failure so susceptible to denial of service attacks or server failure. Performance may be unpredictable because it depends on the network as well as the system. May be management problems if servers are owned by different organizations.

Pipe and filter architecture

- ✧ Functional transformations process their inputs to produce outputs.
- ✧ May be referred to as a pipe and filter model (as in UNIX shell).
- ✧ Variants of this approach are very common. When transformations are sequential, this is a batch sequential model which is extensively used in data processing systems.
- ✧ Not really suitable for interactive systems.

The pipe and filter pattern

Name	Pipe and filter
Description	The processing of the data in a system is organized so that each processing component (filter) is discrete and carries out one type of data transformation. The data flows (as in a pipe) from one component to another for processing.
Example	Figure 6.13 is an example of a pipe and filter system used for processing invoices.
When used	Commonly used in data processing applications (both batch- and transaction-based) where inputs are processed in separate stages to generate related outputs.
Advantages	Easy to understand and supports transformation reuse. Workflow style matches the structure of many business processes. Evolution by adding transformations is straightforward. Can be implemented as either a sequential or concurrent system.
Disadvantages	The format for data transfer has to be agreed upon between communicating transformations. Each transformation must parse its input and unparse its output to the agreed form. This increases system overhead and may mean that it is impossible to reuse functional transformations that use incompatible data structures.
